Can a standardized plant immunomodulator (rice bran arabinoxylan concentrate/MGN-3) increase the effects of MEK and BRAF inhibitors with clinical benefit? Case report of a patient with carcinoma in biliary duct

Tibor Hajto*
Medical University Pecs, Hungary

Abstract

Background: Targeting hyperactive mitogen-activated protein kinase (MAPK) signaling cascade has proven to be an effective treatment for a variety of different cancers. Using an important member of this cascade, namely MEK (mitogen activated extracellular signal regulation kinase) inhibitors, the clinical responses are often transient and complete remission is rarely observed. Outgrowth of resistant clones within progressed tumors appears to be inevitable. Recent immunological and clinical observations suggest that in background of this resistance the tumor-induced disturbance of immunoregulation at least in part may play a role. Namely, it was shown that growth factor receptor signaling pathway inhibitors can increase the immune sensitivity of tumor cells, but they can't activate the down regulated immune effectors. Consequently, the combination of MAPK cascade signaling pathway inhibitors and the immune effectors activating immunomodulators may be a promising new strategy.

Material and methods: In a now 59 years old patient with inoperable (BRAF-mutant) low differentiated adenocarcinoma of biliary ducts after 30GY radiotherapy and two cycles (Gemcitabin+ Cisplatin) chemotherapy a rapid progression of lung, liver and brain metastases were by CT and MR established. Thereafter, a treatment with BRAF+MEK inhibitors (2x150 mg dabrafenib and 1 x 2 mg trametinib) was started. These inhibitors were combined with daily 45 mg/kg rice bran arabinoxylan concentrate (using Biobran/MGN-3) which was shown to be a pathogenic associated molecular pattern (PAMP)-like molecule and can stimulate the type-1 innate immune cells against tumor cells. Results: After the chemotherapy and prior to the start of second line treatment, the patient had a nearly terminal state of her rapidly progressive disease. Eight months after the combination of MEK / BRAF inhibitor and immunomodulator therapy nearly complete remissions of all metastases was established in CT and MR.

Conclusion: This case report may support a hypothesis that MEK / BRAF inhibitors and type-1 immune cells activating immunomodulators together may synergistic inhibit the tumor growth. Further clinical investigations are necessary to clarify this question.

Introduction

MEK (Mitogen activated Extracellular signal regulation Kinase) – inhibitors can down regulate the receptor tyrosine kinase mediated signaling pathway by inhibition of mitogen activated protein kinase /MAPK/ cascade (RAS/RAF/MEK/ERK) which regulates cell proliferation, cell cycle progression and cell migration. Dysregulation of the MAPK cascade occurs in more than one-third of all malignancies, a process that has fostered the development of targeted MAPK pathway inhibitors [1]. Owing to the wide spread activation of this pathway in numerous neoplasms, MEK inhibitors are being studied in combination with other targeted and cytotoxic drugs in a variety of clinical situations [2-4]. MEK inhibitory compounds demonstrated markedly enhanced potency against BRAF (V600E) cancer cells compared to cell lines lacking this oncogenic pathway mutation. In addition, between MEK and BRAF inhibitors exhibit a synergistic effect [5].

Despite the improved outcomes with monoclonal antibodies targeting various members of the MAPK cascade, durable clinical responses are uncommon. Outgrowth of resistant clones within progressed tumors appears inevitable [6]. Recent immunological and clinical observations suggest that in background of this resistance at least in part the tumor-induced disturbance of immunoregulation may play also a role. In spite of an enhanced sensitivity of tumor cells for immunological killing by targeted MAPK pathway inhibitors [7-8] the most important immune effector cells against tumor are parallel not activated.

As it well known, tumor cells are definitively able to escape from the T cell lyse since they exhibit genetic dysregulation related irreversible quantitative and qualitative alterations of their MHC-I antigens [9]. Consequently, growing attention is focusing on the mechanisms of innate immune system which are able to kill tumor cells in a non-MHC-restricted manner and appear to exhibit more reversible escape mechanisms if it is compared with adoptive system. As known, the effector cells of innate immune system are committed in two directions. Type-1 macrophages (M1) and from the monocytes originating type-1 dentritic cells (DC1) generate (in a rigorously regulated cascade system
only for short time) proinflammatory cytokines, IL-12 and activate cytotoxic effector (such as NK and NKT) cells which are potent inhibitors of tumor growth. However, these type-1 cells are defective in tumor patients. Available information suggests that tumor-associated macrophages belong to the prototypic M2 population [10,11]. M2 macrophages and from the plasmacytoid precursors originating DC2 dendritic cells generate IL-4 and IL-10 which facilitate the generation of Th2 cells and inhibit Th1 cells and the type-1 natural system [10]. M2 macrophages and CD2 dendritic cells affect chronic inflammation, promote cell proliferation by producing growth factors and stimulate angiogenesis. Tumor patients can have up to 40% more M2 peripheral monocytes than healthy individuals who have only 10% M2 monocytes [10,11].

As it was mentioned, the dominance of M2 and CD2 cells in tumor patients can lead to an enhanced production of growth factors which are also contribute to the down regulation of the type-1 natural immune cells. It was shown that growth factors can inhibit the NK cytotoxicity against cancer cells by down regulating the expression of the so-called stress-related receptors on tumor cell membrane, namely the Killing Activator Receptor (KAR) binding NKGD2 ligands: UL-16 binding proteins (ULBP1 and ULBP2) or MICA and MICB [7,8]. Taken together these observations, we can conclude that targeted MAPK pathway inhibitors can enhance the sensitivity of tumor cells against immune effectors but they are not able to activate them. Therefore, the hypothesis is arisen as to whether immunomodulators, which are able to activate the (type-1) immune effectors against tumor cells, may improve the effects of the targeted MAPK pathway inhibitors. In this paper, a case report is presented which may support this hypothesis. A patient with inoperable (BRAF-mutant) low differentiated adenocarcinoma of biliary ducts with lung, liver and brain metastases was treated with a combination of MEK and BRAF inhibitors together with evidence based and standardized plant immunomodulator (BioBran/MGN-3) which was shown to stimulate the type-1 natural immune cells. After four months all metastases showed a nearly complete remission which were after 8 months also established.

Material and methods

MEK and BRAF inhibitors

As MEK inhibitor 1 x 2 mg trametinib and as BRAF inhibitor 2x150 mg dabrafenib were given from July 4th 2016 regularly until March 2017 (observation period). The patient was regularly controlled by CT and MR investigations by the Oncological Department of Medical University Debrecen (Hungary).

Standardized rice bran extract (BioBran/MGN-3)

The immunomodulatory drug used in the combinative treatment of the presented patients is BioBran/MGN-3 which is manufactured and supplied by Daiwa Pharmaceutical Co, Ltd, Tokyo, Japan. BioBran/MGN-3 is composed of denaturated hemicellulose, which is obtained by rice bran hemicellulose reacting with multiple carbohydrate-hydrolyzing enzyme from shiitake mushrooms. BioBran/MGN-3 is standardized for its main chemical component: arabinoxylan with a xylose (in its main chain) and with an arabinose polymer (in its side chain). To the presented patient BioBran/MGN-3 was given orally in doses of 45mg/kg at first daily and four months later three times a week. At the same time an immunomodulatory treatment was started with a standardized bran rice arabinoxylan concentrate (BioBran/MGN-3) in doses of 3 g daily for four months and thereafter three times 3 g a week. During this combinative therapy a very rapid remission of all metastases were observed. Figures 1 and 2 show the rapid decreases of tumor markers (CEA and CA19-9) in peripheral blood. After four and eight months nearly complete remissions (CR) of all metastases were also established by CT and MR investigations. Figure 3 represents a CR of a brain metastasis prior the treatment and eight months later.

Discussion

The effect of the immune system on the inhibitory targeting therapy of the tyrosin kinase mediated signaling pathway is poorly understood since very few research results are now available. Although signaling pathway are usually depicted as linear cascades, nearly all signaling pathway are highly interconnected and form networks that allow dynamic regulation of the timing, strength and duration. In addition, both feed forward and feed backward loops provide the means to self-regulation signals. As a consequence, the same signal may induce different outcomes depending on the particular cell state. Consequently, they can inhibit or stimulate in different cells [6]. Interestingly, it

This case report may stimulate an interest for other research groups according to the opinion of the ethics committee.

Results

A now 59 year old patient with inoperable low differentiated adenocarcinoma of biliary ducts had in April 2016 a terminal stage of her disease. By PET/CT investigations multiplex metastases were established in the following organs: lung (S3), bilateral mediastinal, paraoortal, paratracheal, subcarinal, subclavicular lymph nodes, pancreas, hilus of liver and mesenterium. In addition, four brain metastases (three in cerebellum and one in temporal region) were detected by MR investigation. After an irradiation (30 GY WBRT), in Mai/June 2016 two cycles Cisplatin and Gemcetabin were given. At end of June 2016 progressions of all metastases were established and therefore the chemotherapy was stopped. Since by the genetic investigation 15% BRAF (V600E) clinical relevant driver mutation and 22% TP53 (Q165*28) clinical relevant driver mutation were found, at begin of July 2016 1 x 2 mg trametinib MEK inhibitor and 2x150 mg dabrafenib BRAF inhibitor were given. At the end of July 2016 in April 2017 a progressions of all metastases were established and therefore the chemotherapy was stopped. Since by the genetic investigation 15% BRAF (V600E) clinical relevant driver mutation and 22% TP53 (Q165*28) clinical relevant driver mutation were found, at begin of July 2016 1 x 2 mg trametinib MEK inhibitor and 2x150 mg dabrafenib BRAF inhibitor were given. At the same time an immunomodulatory treatment was started with a standardized bran rice arabinoxylan concentrate (BioBrans/MGN-3) in doses of 3 g daily for four months and thereafter three times 3 g a week. During this combinative therapy a very rapid remission of all metastases were observed. Figures 1 and 2 show the rapid decreases of tumor markers (CEA and CA19-9) in peripheral blood. After four and eight months nearly complete remissions (CR) of all metastases were also established by CT and MR investigations. Figure 3 represents a CR of a brain metastasis prior the treatment and eight months later.
Can a standardized plant immunomodulator (rice bran arabinoxylan concentrate/MGN-3) increase the effects of MEK and BRAF inhibitors with clinical benefit? Case report of a patient with carcinoma in biliary duct

Figure 2. Rapid improvement of CEA tumor marker after the start of a treatment with 1x2 mg trametinib (MEK inhibitor) and 2x150 mg dabrafenib (BRAF inhibitor) combined with daily 45mg/kg standardized rice bran arabinoxylan immunomodulator (Biobran).

Figure 3. MR investigations represent a complete remission of a brain metastasis (in cerebellum) after a treatment with 1x2 mg trametinib (MEK inhibitor) and 2x150 mg dabrafenib (BRAF inhibitor) combined with 45mg/kg standardized rice bran arabinoxylan immunomodulator (Biobran).

appears to be a similarity between the regulation of MAPK cascade and the regulation of natural immunity. As it was mentioned above, the effector cells of innate immune system are also committed in two directions [10,11] which also in cascade system can play an important role in the activation and inhibition of cell proliferation. Both protein kinase signaling pathway and innate immunity exist in a basal state and they are activated only as necessary by divergent regulation stimuli [12,13]. The mechanisms for switching between dormant and activate state in both systems can be intricate, but it is probable that both signaling pathways are highly interconnected and form networks. Therefore, it is not surprising that growth factors stimulate the cell proliferation on the one hand and protect the cells (down regulating their ligands) against immune effectors on the other hand inducing a decrease in tumor defense. Consequently, a combination of protein kinase signaling pathway inhibitors and natural effector cells activating immunomodulators may open new perspectives in the tumor therapy. This case report may support this hypothesis. However, in the future we must better learn to manipulate in the regulatory networks, and the timing, strength and duration of responses must be taken with more attention into consideration. For example, the stronger a response, the less possible to give a drug daily, since therapy free intervals can be necessary [13,14].

Pathogenic Associated Molecular Pattern (PAMP) molecules are the best candidates for this combination of targeting therapy with immunomodulation. However, PAMP molecules exist only in the nature (bacteria or plants). The chemistry is not able to produce these configurations. Bacteria have toxic side effects but plants have not. Unfortunately, the best evidence based and standardized immunomodulators without any side effects are plant extracts and they are all over the world registered only as food supplements. There are growing evidences that plant PAMP-like molecules (such as standardized rice bran arabinoxylan concentrate) exhibit a lot of immunological [15-26] and clinical benefit [27-29]. Therefore, further clinical trials are necessary to investigate this beneficial interaction.
